Received (in Cambridge, UK) 28th September 1998, Accepted 29th October 1998

Cobalt(II), zinc(II) and cadmium(II) salts react with the new spacer ligand 2,2′-bi-1,6-naphthyridine 1 to give 2D-planar (4,4) frameworks which interpenetrate such that each grid window of each sheet has two other sheets passing through it with all sheets being equivalent whereas copper(I) tetrafluoroborate and 1 form a 2,1-helicoidal chain with neighboring chains interlocking through an aromatic π–π interaction.

The synthesis of interpenetrating nets and the elucidation of the factors leading to a periodic entanglement is an area of increasing interest. Many interpenetrating structures were obtained from attempts to create porous solid bases on metal coordination polymers. As nature tends to avoid vacuum, identical copies of the frameworks with large openings interpenetrate to fill this empty space rather than to create a single network. In the design of metal–ligand networks rigid and multidentate ligands with pyridine groups feature prominently as building blocks. In our study of functionalized 2,2′-bipyridine-type ligands we look here at the self-assembly process of the new spacer 2,2′-bi-1,6-naphthyridine 1 with various metal salts.

Spacer 1 reacts with cobalt chloride, zinc or cadmium perchlorate in the presence of a slight excess of KSCN in water–ethanol (1 : 1) to give well formed crystals in yields of 50% and above. The products were investigated by single crystal X-ray analysis and correspond to the formula 2[M(NCS)₂(μ-1)₂] (M = Co, Zn, Cd) (matching the C,H,N analytical data). The three M(II) compounds are isostructural. The binaphthyridine ligand assumes the s-trans conformation and bridges between the metal centers. Four ligands of 1 are arranged around the metal in a square-planar fashion and two trans (nitrogen-bound) isothiocyanato ligands complete the octahedral metal coordination sphere. The bonded metal–1 arrangement leads to planar (4,4) nets. Fig. 1 shows an individual metal–ligand grid. The bridged metal–metal distances along the edges of the parallelograms are around 15.76–16.05 Å and the distances along the shorter and longer diagonals are 21.44–21.95 and 23.10–23.43 Å, respectively, depending on the metal. The 2D framework from Fig. 1 is interpenetrated in an inclined mode by symmetry related, identical sheets to give an interlocked 3D structure. The manner of interpenetration is such that each window of each grid has parts of two other sheets passing through it, which we would like to call a 2 × 2 interpenetration (Figs. 2 and 3). It was surprising at first that the rings were large enough and the binaphthyridine rods slim enough to allow the passage of two sheets, when considering the van der Waals surfaces of the aromatic system and the NCS group. A space-
Fig. 3 Stereoview along c of the schematic framework of \([\text{M}(\text{NCS})_2(\mu-1)])\) \((\text{M} = \text{Co}, \text{Zn}, \text{Cd})\), with only the metal center and the central C–C unit of the naphthyridine moiety shown. Sheets of different inclination are drawn with solid or dashed lines, respectively.

Fig. 4 Space-filling drawing of the interpenetration of parts of two sheets through a grid window in \([\text{Zn}(\text{NCS})_2(\mu-1)])\) \((\text{M} = \text{Co}, \text{Zn}, \text{Cd})\).

filling model then illustrated the close \(\pi–\pi\) contact of the naphthyridine moieties (Fig. 4). The knots or metal centers of the intersecting networks do not lie within the plane of the pierced ring but above and below. The nets run either parallel to the \((021)\) or to the \((021)\) plane. The inclination of the sheets is almost perpendicular, the angle ranges from 92.9° for the cadmium grids. A similar mode of interpenetration was so far only reported in the structure of cobalt to 93.7° for the cadmium grids. A bipyridine selectivity in bipyridine nitrogen donor atoms prevent the chelating coordination of two or three ligands of \(I\) with its bipyridine unit in an octahedral complex. A bipyridine selectivity in \(I\) (cuproin group) can, however, be expected towards copper(I). An \(X\)-ray study\(^\dagger\) revealed that the reaction of \(I\) with \([\text{Cu(MeCN)}_2]\)BF\(_4\) in MeCN–CH\(_2\)Cl\(_2\) led to a compound of formula \([\text{Cu(MeCN)}(\mu-1)]\)BF\(_4\).0.5CH\(_2\)Cl\(_2\). A 1D-coordination polymer (Fig. 5) originates from the chelation of the copper center by \(I\) in its \(\pi\)-cis conformation together with the bridging action of the ligand to the next metal through one of its exodentate nitrogen donors. The distorted tetrahedral coordination sphere at copper is completed by an acetoniitrile ligand. The copper–ligand strand assumes a helicoidal conformation following a \(2\alpha\) screw axis. The neighboring parallel strands are of opposite helicity and interlock (interdigitate) through \(\pi–\pi\) interactions of the extended aromatic binaphtyridine system.
